## Abstract

The local stability of several octahedral species  $\text{AlF}_6^{3-}$ ,  $\text{GaF}_6^{3-}$ ,  $\text{InF}_6^{3-}$ ,  $\text{TlF}_6^{3-}$ ,  $\text{TaF}_6^-$ ,  $\text{ZrF}_6^{2-}$ ,  $\text{LaF}_6^{3-}$ , and  $\text{LaCl}_6^{3-}$  was studied using ab initio methods. All systems were found to have minima at octahedral geometries. The electronic stability of these species was considered using electron propagator theory (EPT) and the Møller-Plesset (MP) perturbation scheme. The results indicate that triply-charged molecular species may be electronically stable in the gas phase. Due to the slow convergence of the EPT and MP series and limitation in our one-electron basis set, the final conclusion requires a more advanced theoretical treatment. The doubly- ( $\text{ZrF}_6^{2-}$ ) and singly-charged ( $\text{TaF}_6^-$ ) species were found to possess very high electronic detachment energies of 5.0 and 10.6 eV, respectively.  $\text{TaF}_6^-$  is predicted to be thermodynamically stable and  $\text{ZrF}_6^{2-}$  slightly unstable with respect to the unimolecular decomposition  $\text{ML}_6^{n-} \rightarrow \text{ML}_5^{(n-1)-} + \text{L}^-$ .

## I. Introduction

Multiply-charged anions are challenging species from the point of view of electronic structure theory. Coulomb repulsion between excess negative charges has to be counterbalanced by an advantageous distribution of the total charge to make the system electronically and geometrically stable. The multiply-charged systems are usually thermodynamically unstable but if their lifetimes are long enough, they may be considered as promising candidates for high energy density materials.<sup>1</sup>

The discovery of the dianion of benzol [cd] pyrene-6-one by Dougherty<sup>2</sup> opened the field of doubly-charged molecular species in the gas phase. An excellent review of the subject from both the experimental and theoretical perspective has recently been published by Compton.<sup>3</sup> Briefly, Leiter et al. found doubly charged anions of the oxygen clusters  $(O_2)_n^{2-}$ .<sup>4</sup> Schauer et al. reported on the long-lived  $C_n^{2-}$  ( $n=7$  to 28) species,<sup>5</sup> and dianions of fullerenes were found as well.<sup>6</sup> Korobov et al. estimated the electron affinity of  $PtF_6^-$  to be positive<sup>7</sup> and Maas and Nibbering have produced doubly charged dicarboxylate negative ions.<sup>8</sup>

The challenge to supersede the Coulomb repulsion between two extra electrons provoked theoretical studies as well. Gutsev and Boldyrev estimated maximal value of the second EA of hexafluorides  $MF_6$  in the region of 1-2 eV on the basis of the electronic properties of the  $F_6$  frame.<sup>9a</sup> They also calculated second EA (SEA) of  $PtF_6$  by DV- $X\alpha$  method and found  $SEA=0.7$  eV.<sup>9a</sup> Miyoshi and Sakai predicted positive electron affinities for  $CrF_6^-$  and  $MoF_6^-$ .<sup>10</sup> Recently, Ewig and van Wazer found  $CF_6^{2-}$  to be geometrically metastable at  $O_h$  symmetry.<sup>11</sup> Smaller tetrahedral ( $BeF_4^{2-}$ ) and triangular ( $LiF_3^{2-}$ ,  $NaF_3^{2-}$ ,  $KF_3^{2-}$ ,  $LiCl_3^{2-}$ ,  $NaCl_3^{2-}$  and  $KCl_3^{2-}$ ) dianions consisting of halogen-type ligands and a metal atom have recently been carefully studied by Cederbaum and collaborators.<sup>12-14</sup> They presented convincing evidence for the stability of these species with respect to fragmentation and electron ejection as well as a kinetic stability of these anions. Although these dianions are not stable thermochemically with respect to dissociation into two singly

charged anions, all these species have a high barrier and therefore have a long lifetime. The ionic nature of these systems was recognized as a key factor in compensating Coulomb repulsion between two extra electrons.<sup>13,14</sup> Boldyrev and Simons suggested  $\text{TeF}_8^{2-}$  as the  $\text{MX}_n^{2-}$  species with the largest electron detachment energy,<sup>15</sup> because delocalization of two extra electrons through eight electronegative fluorines occurs. The same authors also searched for linear doubly-charged anions and suggested  $\text{Mg}_2\text{S}_3^{2-}$  as the smallest linear or quasilinear electronically stable species.<sup>16</sup> Second electron affinities of large linear<sup>17</sup> and of trigonal planar<sup>17c</sup> carbon cluster have been found theoretically. However, some free doubly charged anions such as  $\text{CO}_3^{2-}$ ,<sup>13</sup>  $\text{SO}_4^{2-}$ ,  $\text{SeO}_4^{2-}$  and  $\text{TeO}_4^{2-}$ .<sup>18</sup> have been predicted to be electronically unstable notwithstanding that these anions are postulated in solid state, in solution and in molten substances.

As far as the existence of more than doubly charged anions is concerned, neither theory nor experiment has delivered a definite answer yet. Early reports on  $\text{FeF}_6^{3-}$ .<sup>19</sup> were interpreted as harmonic artifacts.<sup>3</sup> Miyoshi and Sakai concluded from their *ab initio* CI calculations that  $\text{AuF}_6^{3-}$  is electronically unstable at octahedral geometries<sup>10b</sup> and Boldyrev and Simons have shown that  $\text{PO}_4^{3-}$ ,  $\text{AsO}_4^{3-}$  and  $\text{SbO}_4^{3-}$  are not electronically stable.<sup>18</sup> A scheme for building multiply charged complex anions has been recently proposed by Scheller and Cederbaum<sup>9b</sup>, and a similar approach was also briefly discussed by Gutsev and Boldyrev.<sup>9a</sup>

In this work we explore local stability of singly-, doubly-, and triply-charged closed-shell octahedral anions  $\text{ML}_6$ . By local stability we understand existence of an  $\text{O}_h$ -symmetry geometrical minimum at which the value of the electron vertical detachment energy (VDE) is positive. Of course, these two features are necessary but not sufficient for long-lived (meta)stability. The latter requires that the closed-shell anion remain electronically stable for a wide range of molecular geometries which are probed in zero-point vibrational motion and that the barrier height for unimolecular decomposition of these species be sufficiently high and wide. These topics are beyond the scope of the present paper. They will be addressed in the future

4

for the most promising candidates selected on the basis of their local stability at octahedral geometries.

## II. Systems of Interest

Octahedral hexafluorides represent a good choice for electronically stable multiply charged anions, because extra charges are distributed through the large number of electronegative ligands and repulsive ligand-ligand interactions are not very high.<sup>20</sup> Fully delocalization of extra electrons is expected for  $\text{MF}_{k+1}^-$ ,  $\text{MF}_{k+2}^{2-}$ ,  $\text{MF}_{k+3}^{3-}$  and for  $\text{MF}_{k+n}^{n-}$  in general cases, where  $k$  is the maximal formal valence of the central atom  $M$  and  $n$  is the negative charge of the multiply charged anion. The central atom  $M$  should be from the group V of the Periodic Table (P-Bi, V-Ta) for singly charged anions ( $k+1=6$ ), from group IV (C-Pb, Ti-Hf) for doubly charged anions, and from group III (B-Tl, Sc-La) for triply charged anions. For all such systems, octahedral closed shell structures are expected.

Quantum chemical calculations (DVM- $X_\alpha$ ) of the nonmetallic hexafluorides  $\text{MF}_6^-$  and hexachlorides  $\text{MCl}_6^-$  have shown high vertical electron detachment energies (VEDE) for these species:  $\text{PF}_6^-$  (6.8 eV),  $\text{AsF}_6^-$  (7.2 eV),  $\text{SbF}_6^-$  (7.0 eV),  $\text{PCl}_6^-$  (4.3 eV),  $\text{AsCl}_6^-$  (5.4 eV) and  $\text{SbCl}_6^-$  (5.6 eV).<sup>21</sup> While experimental electron detachment energies for these anions are not known, the theoretical results agree well with the thermochemical stabilities of noble gas compounds such as  $\text{KrF}^+[\text{SbF}_6]^-$ ,<sup>22</sup>  $\text{Xe}_2\text{F}_3^+[\text{AsF}_6]^-$ ,<sup>23</sup> and others (see Refs 24 and 25).

The doubly negative nonmetallic hexafluoride anion  $\text{CF}_6^{2-}$  is geometrically stable.<sup>11</sup> However, the electronic stability has been studied only for  $\text{SiF}_6^{2-}$ ,<sup>26</sup> what was found to be electronically stable, with a vertical electron detachment energy equal to 0.2 eV. No experimental data is available for the stability of free, doubly charged  $\text{MF}_6^{2-}$  anions, where  $M=\text{C-Sn}$ .

The electronic stability of triply charged  $\text{MF}_{k+3}^{3-}$  anions with nonmetallic central atoms has not yet been reported.

Unusually high first electron affinities of hexafluoride molecules containing transition metal atoms were recognized long ago.<sup>27,28,29</sup> For instance, the electron affinity of  $\text{AuF}_6$  is believed to

be ca. 10 eV.<sup>27,29</sup> Theoretical calculations of Gutsev and Boldyrev<sup>20</sup> confirm a high electron affinity of all 3d, 4d and 5d metal hexafluoride species but also provided a theoretical explanation for the unusual electron affinities of  $\text{VF}_6$ ,  $\text{NbF}_6$ , and  $\text{TaF}_6$  as well as for hexafluorides of the metals from the end of the transition period ( $\text{CuF}_6$ ,  $\text{AgF}_6$ ,  $\text{AuF}_6$ , see Ref. 20 for details). Miyoshi and Sakai predicted the dianions  $\text{CrF}_6^{2-}$  and  $\text{MoF}_6^{2-}$  to be electronically stable at octahedral geometries.<sup>10</sup>

We believe that electronic stability could be further increased by arranging a closed-shell, ionicity-enhancing structure for multiply charged anions. This can be achieved by a proper choice of the central atom. Indeed, recent theoretical studies on thermochemical properties of doubly-charged hexahalogenometallates involving Ti, Zr, and Hf demonstrated their significant stability with respect to the metal atom plus three halogen molecules.<sup>30</sup> These promising results were obtained, however, at low theoretical levels, motivating us to extend the investigations to: a) higher levels of theory, b) analogous closed-shell singly- and triply-charged systems.

We choose highly electropositive, bulky transition metals such as Ta, Zr, and La for the singly-, doubly-, and triply-charged anions, respectively, to ensure highly ionic character in the coordinated complex and to make the distance between the negatively charged ligands as large as possible. Hf would be more consistent with the choice of Ta and La, but it is well known that chemical properties and bond distances are practically the same for the hafnium and zirconium atoms.<sup>31</sup>

Symmetry properties and orbital energies of the metal M and ligand L allow us to make an educated guess about the properties of the molecular orbitals in  $\text{ML}_6^{n-}$ . In Table 1 we show the symmetry-adapted orbitals (SAO) resulting from the valence atomic orbitals (AO), as well as orbital energies in M and L. The orbital energies permit prediction of the ordering and nature of the molecular orbitals in the  $\text{ML}_6^{n-}$  complexes. In particular, it is clear that high-energy, occupied molecular orbitals will be dominated by the ligands' np-type AO's. Mixing with the M orbitals will be largest for Ta and smallest for La. The ligands' np orbitals may be separated into two

groups: parallel ( $np\parallel$ ) and perpendicular ( $np\perp$ ) to the ML bond. The  $np\parallel$  group contains orbitals of the same symmetry as the valence orbitals of the M center, hence bonding interaction can develop. On the other hand, in the  $np\perp$  group only the  $t_{1u}$  orbital can interact, presumably in an antibonding manner, with the M valence counterpart. All of the other ligand orbitals are nonbonding. We conclude that a few highest occupied orbitals of the closed-shell  $MX_6^{n-}$  complex will possess either a nonbonding ( $t_{1g}$ ,  $t_{2u}$ ,  $t_{2g}$ ) or antibonding ( $t_{1u}$ ) character and that the doublet ground state of the  $ML_6^{(n-1)-}$  system will be triply degenerate at the  $O_h$  geometry.

Based on such an analysis, we selected for our calculations the following triply charged anions:  $AlF_6^{3-}$ ,  $GaF_6^{3-}$ ,  $InF_6^{3-}$ ,  $TlF_6^{3-}$ ,  $LaF_6^{3-}$  and  $LaCl_6^{3-}$  as well as the doubly charged  $ZrF_6^{2-}$  and singly charged  $TaF_6^-$ . All of these systems satisfy the  $MF_{k+3}^{3-}$ ,  $MF_{k+2}^{2-}$  and  $MF_{k+1}^{-}$  rules (see above).

### III. Computational Aspects

#### A. Transition Metal Anions.

For  $LaF_6^{3-}$ ,  $LaCl_6^{3-}$ ,  $ZrF_6^{2-}$ ,  $TaF_6^-$ ,  $LaF_5^{2-}$ ,  $LaCl_5^{2-}$ ,  $ZrF_5^-$ ,  $TaF_5$ ,  $LaF_4^-$ ,  $LaCl_4^-$ ,  $ZrF_4$  and  $TaF_4^+$  species, we used the relativistic, compact effective potentials of Stevens et al. together with their valence, energy-optimized, shared-exponent, contracted gaussian basis sets, which we label SBKJ.<sup>32</sup> For the M atoms, the  $(n-1)s$ ,  $(n-1)p$ ,  $ns$ ,  $np$ , and  $(n-1)d$  orbitals are chemically active and take advantage of the double-zeta sp and triple zeta d basis sets. For the L atoms, only the valence  $ns$  and  $np$  orbitals are chemically active, and they are described within a double-zeta quality basis set.

Next, the SBKJ basis sets were supplemented with different sets of diffuse functions. The resulting differences in molecular geometries and Koopmans' theorem predictions of electron detachment energies were carefully monitored. For each M we tested one- and for each L one- and two-term sets of diffuse functions. The exponents of the one-term diffuse basis sets were taken to be equal to 1/3 of the lowest exponent in the original basis. For the two-term

diffuse sets, a geometrical progression was assumed with the progression constant equal to 2.4. Numerical tests described in the next Section suggested use of the original SBKJ basis set supplemented with one set of diffuse functions on the L's only. The resulting basis set for  $ML_6^{n-}$  complexes, labeled SBKJ+diff, consists of 106 contracted gaussian basis functions. It should be stressed that due to the absence of polarization functions, our electron detachment energies are expected to be underestimated.

We performed geometry optimization for the octahedral  $ML_6^{n-}$  complexes with the SBKJ and SBKJ+diff basis sets using the GAMESS program package.<sup>33</sup> Gradient geometry optimization<sup>34</sup> was followed by calculation of the numerical hessian matrix. Normal mode analyses were performed and IR intensities were then calculated.

We calculated two quantities that characterize the charge distribution in the multiply charged anions. First, the radial extent of the distribution is characterized by the mean value of  $R^2$  ( $\langle R^2 \rangle$ ). Second, the effective charges assigned to the M and L atoms were determined from the fit to the electrostatic potential at points selected according to the Merz-Singh-Kollman scheme.<sup>35</sup> For atomic radii, we used 1.34, 1.45, 1.69 Å for Ta, Zr, and La, respectively;<sup>31</sup> for the halogens we used the default values (1.35 Å (F) and 1.70 Å (Cl)).<sup>36</sup> These calculations were performed using the Gaussian 92 package<sup>36</sup> with the SBKJ+diff. basis.

Vertical detachment energies were calculated directly, using the electron propagator theory (EPT) approach [37-42], and indirectly, i.e., calculating the energy of the  $n$ -electron closed-shell anion and  $(n-1)$ -electron open-shell species using commonly available Hartree-Fock (HF) and the Møller-Plesset perturbation theory (MP) methods.<sup>33,36</sup>

In the EPT approach, two types of self-energy approximations are employed. In the first, second order poles are calculated; these results, designated by the abbreviation EPT2, typically exaggerate electron correlation effects. The second method includes all third order terms and many infinite order terms as well. Energy-independent terms through third order are added to an energy-dependent self-energy that includes all ring and ladder diagrams

through all orders in the fluctuation potential.<sup>43</sup> This method is therefore identified by the abbreviation EPT3+. Third-order methods have been thoroughly examined for electron affinities.<sup>40,44</sup> While the fluoride anion requires additional terms in order to obtain an accurate detachment energy,<sup>44</sup> third order methods are generally reliable for fluorine-containing compounds.<sup>38</sup> The usual pole-search algorithms for second order have been used.<sup>39</sup> For EPT3+ calculations, a new algorithm, based on eigenvalue procedures used in configuration interaction calculations, has been employed.<sup>45</sup> A modified version of the EPT90 code<sup>46</sup> was used to perform these calculations.

Indirect calculations of VDE's were restricted to the electronic state of  $ML_6^{(n-1)-}$  obtained by the removal of an electron from the highest occupied molecular orbital (HOMO) of  $ML_6^{n-}$ . The results discussed in the next Section demonstrate that the ordering of the electronic states of  $ML_6^{(n-1)-}$  predicted on the basis of the Koopmans' theorem remains the same in the EPT calculations.

We started from one-configuration calculations to determine the relaxation correction to the Koopmans' theorem prediction. Calculations for the triply-degenerate doublet state of the neutral were performed in two ways. First, a symmetry-unbroken solution was obtained with the hole delocalized over six ligands. This was achieved in the state-averaged (SA) SCF calculation<sup>47</sup> with three configuration state functions involved. It has been reported, however, that single configuration calculations with a core<sup>48</sup> or valence<sup>49</sup> hole delocalized over equivalent atoms may produce unphysical electron binding energies. More reliable results were obtained when the hole was localized in one configuration calculation, i.e., when a symmetry broken solution was produced.<sup>48,49</sup> Hence, we reinforced the SA SCF calculation with UHF calculations in which we allowed for localization of the hole on one ligand. Of course, after inclusion of correlation effects, both single-configuration approaches should lead to the same final result. Our correlated MPn ( $n=2,3,4$ ) calculations were performed with the UHF reference function.<sup>36</sup>

## B. Nontransition Element Hexafluorides

Bond lengths and harmonic frequencies for the isoelectronic  $\text{AlF}_6^{3-}$ ,  $\text{GaF}_6^{3-}$ ,  $\text{InF}_6^{3-}$  and  $\text{TlF}_6^{3-}$  as well as for  $\text{AlF}_3$ ,  $\text{GaF}_3$ ,  $\text{InF}_3$ ,  $\text{TlF}_3$ ,  $\text{AlF}_4^-$ ,  $\text{GaF}_4^-$ ,  $\text{InF}_4^-$  and  $\text{TlF}_4^-$  have been obtained using RHF approximation and the Los Alamos Pseudopotentials,<sup>50</sup> which we label LAP. We used Dunning's valence double-zeta basis set (9s5p/3s2p) for the fluorine atoms<sup>51</sup> and a valence 2s2p basis sets for the aluminum, gallium, indium and thallium,<sup>50</sup> extended by polarization d-functions on all atoms (LAP/DZ+d) and diffuse s- and p-functions on the fluorine atoms (LAP/DZ+d+diff.). Exponents for the polarization d-functions 0.198 (Al), 0.207 (Ga), 0.160 (In) and 0.146 (Tl) were taken from Ref. 52 and exponents of the diffuse s- and p-functions 0.074 were taken from Ref. 53. All calculations with Los Alamos pseudopotential were performed using the Gaussian 92 package.<sup>36</sup>

## IV. Results

### A. Nontransition metal hexafluorides.

The results of SCF (at LAP/DZ+d and LAP/DZ+d+diff.) geometry optimization and frequency calculations are presented for  $\text{AlF}_3$ ,  $\text{GaF}_3$ ,  $\text{InF}_3$  and  $\text{TlF}_3$  in Table IIA, for  $\text{AlF}_4^-$ ,  $\text{GaF}_4^-$ ,  $\text{InF}_4^-$  and  $\text{TlF}_4^-$  in Table IIB and for  $\text{AlF}_6^{3-}$ ,  $\text{GaF}_6^{3-}$ ,  $\text{InF}_6^{3-}$  and  $\text{TlF}_6^{3-}$  in Table IIC. Experimental data are available for  $\text{AlF}_3$ ,  $\text{GaF}_3$ ,  $\text{AlF}_4^-$  and for all triply charged hexafluorides. Our optimized bond lengths and frequencies are nearly the same for the LAP/DZ+d and LAP/DZ+d+diff. calculations, and agree with available experimental data within 0.05 Å for bond lengths and 30  $\text{cm}^{-1}$  for vibrational frequencies (Tables IIA and IIB).

The optimized bond lengths  $R(\text{Al-F})=1.89\text{-}1.91$  Å of  $\text{AlF}_6^{3-}$ ,  $R(\text{Ga-F})=1.92\text{-}1.96$  Å of  $\text{GaF}_6^{3-}$ ,  $R(\text{In-F})=2.05\text{-}2.06$  Å of  $\text{InF}_6^{3-}$  and  $R(\text{Tl-F})=2.22\text{-}2.24$  Å of  $\text{TlF}_6^{3-}$  can be compared with the experimental data for these anions in crystal salts  $R(\text{Al-F})=1.81$  Å in  $\text{Na}_3\text{AlF}_6$ ,<sup>54</sup>

$\text{Cs}_2\text{NaAlF}_6$ ;<sup>55</sup>  $R(\text{Ga-F})=1.89 \text{ \AA}$  in  $(\text{NH}_4)_3\text{GaF}_6$ ;<sup>56</sup>  $R(\text{In-F})=2.04 \text{ \AA}$  in  $(\text{NH}_4)_3\text{InF}_6$ <sup>57</sup> and  $R(\text{Tl-F})=1.96 \text{ \AA}$  in  $\text{Rb}_3\text{TlF}_6$ .<sup>57</sup> From these data one can see that the difference between the calculated and corresponding experimental bond lengths is high for  $\text{AlF}_6^{3-}$  (0.1  $\text{\AA}$ ), decreases in  $\text{GaF}_6^{3-}$  (0.03-0.07  $\text{\AA}$ ) and further decreases for  $\text{InF}_6^{3-}$  (0.01-0.02  $\text{\AA}$ ), but the difference is very large in  $\text{TlF}_6^{3-}$  (0.26-0.28  $\text{\AA}$ ). Why our bond length is too high for  $\text{TlF}_6^{3-}$  is not clear at this time. The experimental bond lengths increase from  $\text{AlF}_3$  to  $\text{AlF}_6^{3-}$  and from  $\text{GaF}_3$  to  $\text{GaF}_6^{3-}$  by approximately 0.18  $\text{\AA}$ , and the same variation is found in our calculations. From this point of view, the calculated difference in bond lengths (0.24  $\text{\AA}$ ) for  $\text{TlF}_3$  and  $\text{TlF}_6^{3-}$  may not be unreasonable.

All of  $\text{AlF}_6^{3-}$ ,  $\text{GaF}_6^{3-}$ ,  $\text{InF}_6^{3-}$  and  $\text{TlF}_6^{3-}$  have local minima at the octahedral structure, and thus all of the computed vibrational frequencies are real (see Table IIC). Therefore, if we keep the number of electrons constant, these trianions are geometrically stable. However, the disagreement between our calculated and the corresponding vibrational frequencies of crystal salts is unexpectedly high (80-160  $\text{cm}^{-1}$ ). At the same level of theory the maximum difference between experimental and calculated frequencies for  $\text{AlF}_3$ ,  $\text{AlF}_4^-$  and  $\text{GaF}_3$  is only 30  $\text{cm}^{-1}$  (see Tables IIA and IIB). Moreover, when we improved the basis sets and included diffuse functions, the disagreement became even worse.

We suspect that these large differences may be related to the electronic instability of the anions. In particular, the  $\text{MX}_6$  in the solid state would probably bear a smaller excessive charge than that assumed in our ab initio calculations. The smaller excess charge would make the species less floppy, in agreement with the experimental/theoretical difference. Moreover, the electronic instability may enhance the coupling between the vibrations of  $\text{MX}_6$  and the neighboring species. Therefore, some vibrations should be assigned to the isolated anions, but rather to a collective motion also involving the cations and even the lattice as a whole. If so, the so called "experimental force fields"<sup>58,59</sup> for these anions should be revised.

The orbital energies of the  $t_{1g}$ -HOMO are positive for  $\text{AlF}_6^{3-}$  and  $\text{GaF}_6^{3-}$  and therefore both these anions are certainly electronically unstable, because, according to our experience, when electron relaxation and electron correlation are taken into account the electronic stability of multiply charged anions decreases.  $\text{InF}_6^{3-}$  and  $\text{TlF}_6^{3-}$  both have negative orbital energies of the  $t_{1g}$ -HOMO: -0.41 eV and -0.20 eV, respectively. Therefore, both the anions are electronically stable at the Koopmans level of theory. However, previous ab initio calculation for  $\text{BeF}_4^{2-}$ ,<sup>12</sup>  $\text{MX}_3^{2-}$ , where  $\text{M}=\text{Li-K}$  and  $\text{X}=\text{F-Cl}$ ,<sup>13,14</sup>  $\text{SeO}_4^{2-}$  and  $\text{TeO}_4^{2-}$ ,<sup>18</sup> have shown that electron correlation and electron relaxation corrections decrease electronic stability by 1-2 eV. Therefore we conclude that all free  $\text{AlF}_6^{3-}$ ,  $\text{GaF}_6^{3-}$ ,  $\text{InF}_6^{3-}$  and  $\text{TlF}_6^{3-}$  are not electronically stable species.

## B. Transition metal hexafluorides.

The results of SCF geometry optimization for  $\text{TaF}_6^-$ ,  $\text{ZrF}_6^{2-}$ ,  $\text{LaF}_6^{3-}$ , and  $\text{LaCl}_6^{3-}$  closed-shell anions with the SBKJ basis set are presented in Table IID. We also report vibrational frequencies (all real) and IR intensities for these species. We have demonstrated that augmenting the SBKJ set with diffuse functions on X and/or M affects the M-L equilibrium distance by less than 0.01 Å. Results of Cederbaum and collaborators indicate that correlation effects barely affect equilibrium geometries of tetrahedral and triangular doubly charged anions.<sup>12-14</sup> Hence, our further calculations were performed at the SBKJ equilibrium geometries.

Calculated geometries and vibrational frequencies for isolated  $\text{TaF}_6^-$  and  $\text{ZrF}_6^{2-}$  anion are in good agreement with available experimental data (see Table IID) from the solid phase. The discrepancies in frequencies are less than 25  $\text{cm}^{-1}$  for  $\text{TaF}_6^-$ . For  $\text{ZrF}_6^{2-}$ , the SCF/SBKJ frequencies are systematically lower than the solid state data,<sup>60,61</sup> but the discrepancies do not exceed 45  $\text{cm}^{-1}$ . For triply charged  $\text{LaF}_6^{3-}$  and  $\text{LaCl}_6^{3-}$  species, however, discrepancies are more significant (108  $\text{cm}^{-1}$  for valent symmetrical vibration, Table IID). These triply charged anions are electronically barely stable or even unstable (see below). This may cause larger

disagreement with experimental data (see above discussion for nontransition metal hexafluorides).

The values of  $\langle R^2 \rangle$  presented in Table II demonstrate how the spatial extent of the electronic charge distribution changes in the sequence of multiply charged but otherwise similar anions. For comparison, the values of  $\langle R^2 \rangle$  for  $F^-$  and  $Cl^-$  are 15.8 and 36.9 a.u., respectively. As expected, the spatial extent is particularly large in the case of three excess electrons. Interestingly, inspection of the orbitals in the HOMO region indicates that they are not dominated by the most diffuse functions which are available in the basis set. We interpret this feature as the first indication that the triply charged anion may be electronically stable. Effective atomic charge, presented in the fourth column of Table II, reflects the increasing ionic character in the Ta, Zr, La sequence. Replacing F's by Cl's increases substantially the spatial extent of the electronic charge distribution and slightly decreases the ionicity of the complex. The reported values of effective atomic charges allow consideration of  $ZrF_6^{2-}$ ,  $LaF_6^{3-}$ , and  $LaCl_6^{3-}$  as ionic complexes with six singly charged ligands coordinated to the  $M(6-n)^+$  core, consistent with the ionic model of Cederbaum and collaborators.<sup>13,14</sup>

Vertical detachment energies from the HOMO orbital of the closed-shell species are reported in Table III. All the species are electronically stable at the Koopmans theorem level. Augmenting the SBKJ basis set with one set of L(sp) diffuse functions centered on L's may change the HOMO orbital energy even by 0.4 eV ( $LaF_6^{3-}$  case). However, further extensions of the basis set with two sets of ligand diffuse functions or one set of M diffuse functions changes the HOMO orbital energy by at most a few hundredths of an eV. This further supports our choice of SBKJ+diff as the basis set for the production runs.

The SCF relaxation energies for  $F^-$  and  $Cl^-$  calculated within the SA SCF and UHF procedures are very large but quite similar. For  $MF_6^{n-}$ , however, the SA SCF relaxation energies do not exceed 0.65 eV. At the same time the UHF relaxation energies may be as large as 3.51 eV and the triply charged anions are predicted to be unstable at

this level of theory. Interestingly, the relaxation effects are much smaller for  $\text{LaCl}_6^{3-}$ , as they are for  $\text{Cl}^-$  compared to  $\text{F}^-$ .

There is a significant difference in the magnitude of the relaxation contribution to the VDE when the UHF or SA SCF scheme are applied, see also Refs. 48, 49 and 14b. In all of the fluoride-containing species studied here, the UHF based VDE is further from the correlated result than the SA SCF prediction; the latter however, systematically overestimates the magnitude of the binding energy in all  $\text{ML}_6^{3-}$  systems. Hence, neither the symmetry-broken UHF nor the SA SCF delivers reliable VDE's.

Inclusion of correlation effects at the Møller-Plesset level of theory increases the detachment energy in comparison with the UHF predictions. The convergence in consecutive orders of the perturbation theory is, however, not uniform, with the MP2 and MP4 results being usually close to each other. The similarity between the MP2 and MP4 VDE's should not be considered as a firm argument that the converged result has been reached. For instance, for  $\text{CN}^-$ , the MP2 and MP4 results are quite similar but inaccurate.<sup>45</sup> The experimental electron detachment energies for  $\text{F}^-$  and  $\text{Cl}^-$  are 3.40 and 3.62 eV, respectively.<sup>62</sup> Therefore, our MP4 results for these species are off by 0.28 and 0.50 eV, respectively. Hence, the electronic instability of  $\text{LaF}_6^{3-}$  and  $\text{LaCl}_6^{3-}$  predicted at the MP4 level is probably misleading.

Vertical detachment energies calculated within the EPT method also exhibit a non-uniform convergence. The EPT2 correction to the Koopmans theorem result is destabilizing and overshoots. Triply-charged anions are unstable at this level of theory. The EPT3+ results are, however, much more positive, predicting  $\text{LaF}_6^{3-}$  to be electronically stable and  $\text{LaCl}_6^{3-}$  marginally unstable. Since the EPT3+ result for  $\text{Cl}^-$  is underestimated by 0.21 eV, we think that  $\text{LaCl}_6^{3-}$  may be electronically stable. Contrariwise, the EPT3+ result for  $\text{F}^-$  puts the electronic stability of  $\text{LaF}_6^{3-}$  in question. The slow convergence of EPT methods in the case of  $\text{F}^-$  is well documented.<sup>44</sup> An encouraging observation is that EPT VDE's of the fluorine-containing compounds are usually reliable.<sup>38</sup>

Our MP4 and EPT3+ results demonstrate that  $\text{TaF}_6^-$  is a striking example of a superhalogen, i.e., an anion with the electron binding energy exceeding that of  $\text{Cl}^-$  ion.<sup>21,63,64</sup> Its EPT3+ value of VDE (10.61 eV) is at least as large as the experimental result of  $10 \pm 0.5$  eV for the "unusual"  $\text{AuF}_6^-$  species.<sup>27,28</sup> Previously calculated  $\text{VDE}(\text{TaF}_6^-) = 8.4$  eV by DV- $X_\alpha$  method<sup>20a</sup> is somewhat underestimated.

Interestingly, in the doubly-charged molecular anion  $\text{ZrF}_6^{2-}$ , the second excess electron is bound more strongly than the first excess electron in the leading monoatomic anion  $\text{Cl}^-$ . This conclusion is valid both at the MP4 and EPT3+ level. The value of 4.99 eV (EPT3+ result) is comparable with the estimation (4.9-5.1 eV) of VDE in  $\text{TeF}_8^{2-}$ , claimed to be the  $\text{MX}_n^{2-}$  dianion with the largest VDE.<sup>15</sup> Since many ionic solids containing  $\text{ZrF}_6^{2-}$  dianion are known,<sup>30a</sup> one could try to produce this unusual species in sputtering experiments.

As expected from the symmetry analysis and orbital energies presented in Table 1, for all  $\text{MX}_6^{n-}$  species the three highest occupied molecular orbitals are of  $t_{1u}$ ,  $t_{1g}$ , and  $t_{2u}$  symmetry. In Table IV, VDE's for the transitions to the doublet  $T_{1u}$ ,  $T_{1g}$ , and  $T_{2u}$  states are reported for all fluoride-containing complexes. The ordering of these states depends on the system, but for every species it remains the same at the KT and EPT3+ level. More interestingly, the separation between the first and third state predicted at the KT level remains within 0.04 eV of the separation at the EPT3+ level. Moreover, the pole strengths in the EPT3+ calculations, which are reported in Table IV, never drop below 0.91. These two factors support our claim that not only doubly- but also triply-charged octahedral anions may be electronically stable.

Finally, we briefly discuss thermodynamic stability of the  $\text{ML}_6^{n-}$  species with respect to two dissociation steps:

Equilibrium geometries, vibrational frequencies, and IR intensities for the product molecules  $\text{ML}_5^{(n-1)-}$  ( $D_{3h}$ ) and  $\text{ML}_4^{(n-2)-}$

( $T_d$ ) were determined at the SCF/SBKJ level and are reported in Table V.

Energy changes for the (1a) and (1b) reactions were determined at the MP2 level with the SBKJ+diff basis sets and are reported in Table VI. In these MP2 calculations, the four lowest occupied orbitals were not correlated. The results demonstrate that the decomposition of  $ML_6^{3-}$  will be exothermic in both reaction steps. The amount of energy released, 533 and 475 kJ/mol for  $LaF_6^{3-}$  and  $LaCl_6^{3-}$ , respectively, is significant and the entropy factor would increase exothermicity. Our results also indicate that  $LaF_5^-$  and  $LaCl_5^{2-}$  species are promising candidates for electronically and geometrically stable penta-coordinate dianions. Their KT values of VDE are 5.4 and 4.2 eV, respectively.

The 1a decomposition of  $ZrF_6^{2-}$  is predicted to be slightly exothermic. The product  $ZrF_5^-$  is thermodynamically stable. In addition,  $ZrF_5^-$  displays properties of a remarkable penta-coordinate superhalogen. Its VDE at the KT level is 11.4 eV.

Finally,  $TaF_6^-$ , which was recognized above as a remarkable hexa-coordinated superhalogen, is thermodynamically stable with respect to the decompositions 1a and 1b.

## V. Summary

We have studied local geometric and electronic stability of the closed-shell octahedral species  $AlF_6^{3-}$ ,  $GaF_6^{3-}$ ,  $InF_6^{3-}$ ,  $TlF_6^{3-}$ ,  $TaF_6^-$ ,  $ZrF_6^{2-}$ ,  $LaF_6^{3-}$ , and  $LaCl_6^{3-}$  using ab initio methods.

We have found that local minima exist for these species at octahedral geometries.

$AlF_6^{3-}$  and  $GaF_6^{3-}$  ions have positive HOMO energies and therefore are not electronically stable even at the Koopmans theorem level.  $InF_6^{3-}$  and  $TlF_6^{3-}$  have negative orbital energies of -0.41 eV and -0.21 eV. Because both energies are low and correction from electron correlation and electron relaxation should destabilize both anions by 1-2 eV, we concluded that all four of these triply charged anions are not electronically stable species.

Calculated vibration frequencies for electronically unstable  $\text{AlF}_6^{3-}$ ,  $\text{GaF}_6^{3-}$ ,  $\text{InF}_6^{3-}$  and  $\text{TlF}_6^{3-}$  species are underestimated by 100-160  $\text{cm}^{-1}$ , while for electronically stable species ( $\text{AlF}_3$ ,  $\text{AlF}_4^-$ ,  $\text{GaF}_3$ ,  $\text{ZrF}_4$  and  $\text{ZrF}_6^{2-}$ ), these numbers differ from experimental data by no more than 45  $\text{cm}^{-1}$ . We consider these larger disagreements for triply charged anions to be a result of a) different excess negative charges operative in the solid state and b) essential interactions between vibrational modes of isolated anions and the lattice (cations) for electronically unstable anions. Therefore, experimental vibrational spectra for solids containing multiply charged electronically unstable anions should be treated by taking collective modes, including cations and anions, into account.

Electronic stability of  $\text{TaF}_6^-$ ,  $\text{ZrF}_6^{2-}$ ,  $\text{LaF}_6^{3-}$ , and  $\text{LaCl}_6^{3-}$  was investigated using the electron propagator and the Møller-Plesset perturbation approach. Our results indicate that triply-charged molecular anions may be electronically stable as isolated species. The convergence of the EPT and MP series was found to be slow but the error analysis for isolated  $\text{F}^-$  and  $\text{Cl}^-$  supports the hypothesis of electronic stability of  $\text{ML}_6^{3-}$  species studied here.

Both triply-charged species were found to be thermodynamically unstable with respect to two consecutive unimolecular decompositions. The electronic energy released would be 533 and 475 kJ/mol for  $\text{LaF}_6^{3-}$  and  $\text{LaCl}_6^{3-}$ , respectively. Hence they are promising components of the high energy density propellants.

More advanced ab initio calculations as well as exploration of geometries probed in the zero-point vibrational motion of  $\text{ML}_6^{3-}$  species are required to make conclusions about the long-lived metastability of these interesting species.

The  $\text{ZrF}_6^{2-}$  species was found to be a promising candidate for an extremely stable molecular dianion. Its VDE value amounts to 4.99 eV at the EPT3+ level of theory and relatively low thermodynamic instability with respect to  $\text{ZrF}_5^- + \text{F}^-$  supports our claim.

The  $\text{TaF}_6^-$  species was recognized as a thermodynamically stable superhalogen with the VDE value of 10.6 eV at the EPT3+ level of theory.

Table I. Symmetry-adapted orbitals (SAO) that can be formed from the ligand (L) and metal (M) atomic orbitals (AO) for octahedral complexes  $ML_6^{n-}$ . Orbital energies of L and M in a.u. are calculated with the SBKJ+diff basis set. Symbols  $np_{||}$  and  $np_{\perp}$  denote ligands'  $np$  orbitals parallel and perpendicular to the ML bond, respectively.

Atom	AO	SAO	Orbital energy (a.u.)
L	$ns$	$a_{1g} + e_g + t_{1u}$	-1.58(F) -1.07(Cl)
L	$np_{  } ML$	$a_{1g} + e_g + t_{1u}$	-0.73(F) -0.51(Cl)
L	$np_{\perp} ML$	$t_{1g} + t_{1u} + t_{2g} + t_{2u}$	-0.73(F) -0.51(Cl)
M	$(m-1)s$	$a_{1g}$	-3.20(Ta) -2.51(Zr) -1.82(La)
M	$(m-1)p$	$t_{1u}$	-1.78(Ta) -1.50(Zr) -1.05(La)
M	$(m-1)d$	$e_g + t_{2g}$	-0.31(Ta) -0.30(Zr) -0.23(La)
M	$ms$	$a_{1g}$	-0.25(Ta) -0.21(Zr) -0.18(La)
M	$mp$	$t_{1u}$	-0.08(Ta) -0.13(Zr) -0.16(La)

Table IIA. SCF optimized central atom-ligand distances ( $R_{ML}$  in Å), vibrational frequencies ( $\text{cm}^{-1}$ ), and IR intensities ( $D^2/(\text{Å}^2 \text{amu})$ ; in parenthesis) for the octahedral closed-shell anions. Spatial extent of the SCF electronic charge distribution  $\langle R^2 \rangle$  in a.u. Effective atomic charge (Mulliken) on the ligand atom ( $Q_L$ ) in a.u.
